...Abstract: papers. Transfer tapes are available for applications demanding very thin adhesive layers. Natural or synthetic **water** **soluble** polymers such as dextrine, gelatine, vinyl **pyrrolidone** or **polyvinyl** alcohol are not suitable for PSA formulation. High performance **water** **soluble** splicing tapes can be made using polyacrylate based PSAs. Latest developments include alkylacrylate and acrylic...

PREMISE Offers PCOs a Host of ADVANTAGES
26c

Pest Control, p26C
April, 1998

TEXT:

Since Premise was registered by the Environmental Protection Agency (EPA) on Feb. 8, 1995, for the control of all economically damaging subterranean termite species affecting structures prior to and after construction, the product has caught on very rapidly with pest control operators (PCOs) for several reasons.

The fact of the matter is, 'Premise is not your father's termiticide.' The product, which is manufactured by Bayer Corp., Kansas City, Mo., offers several

distinct advantages over today's competing termiticides, as well as those from yesteryear.

Premise brings several advantages to the marketplace that PCOs have

not seen before. These include:

1. A 'treated zone' around the structure as opposed to a 'barrier.'
2. A unique mode of action.
3. No odor.
4. Innovative packaging that provides easy handling.
5. Control over a wide variety of termites. (In addition, carpenter ant control was recently added to the label.)

NON-REPELLENT TREATED ZONE - Premise offers PCOs a non-repellent treated zone, as opposed to a repellent barrier treatment. The difference is this, when Premise is applied beneath and around a structure, it is distributed throughout the soil in a process referred to as Lateral Soil Movement.

This is important for PCOs to consider. When termites come to a typical termiticide barrier, they often forage until they find a small break and then move through the break into the structure. Premise, on the other hand, provides wider distribution in the soil. Because of its moderate ****water**** ****solubility****, ****imidacloprid****, the active ingredient in Premise, moves with the wetting front of the soil. Then as the soil dries, Premise binds with soil particles, establishing a continuous treated zone.

Looking at this advantage, Michael Cavanaugh, from Cavanaugh's Exterminating Co., Freehold, N.J., says, 'We like the fact that Premise offers a broader treatment area, what Bayer calls its treated zone.' Termites are allowed to pass through into the treated area to pick up the termiticide.

'With traditional termiticides, if there is a break in the barrier, and the termiticide doesn't get to it, the termites will get through that area.'

MODE OF ACTION - superior mode of action is also an important consideration. Traditionally, when termites come into contact with the other termiticides on the market, they are either repelled or killed.

Premise brings a different mode of action to the pest control industry. The termites don't know that they have encountered Premise in the soil until it's too late, and as a result, their actions are different. As soon as the termites contact Premise, they stop feeding immediately. The termites also become disoriented and stop interacting socially as Premise affects their nervous systems.

However, the product doesn't stop working there. A mode of action called Premise Plus Nature takes effect, which means that termites succumb to disease and ultimately die through contact with naturally occurring organisms found in the soil.

These two modes of action set off a series of events in the colony, including no feeding, grooming or socializing and then, death.

'The area we really found it effective in, and we felt that it was because it doesn't have a repelling action, is in high moisture areas, such as in walls. The termites seem to continue working back to the ground, and Premise kills out the colonies. With other termiticides, the termites seem to sense the chemical and keep on feeding in the walls,' states Frank Strickland, from A&A Termite & Pest Control, Marietta, Ga.

ODOR-FREE - Jeff Annis, from Advanced Services, Augusta, Ga., also likes what happens when he uses Premise. In addition, he reports that the product has no odor and is easy to handle.

'Our original reason for using it was the mode of action,' Annis states. 'Premise is a completely different type of termiticide. It works very well on the termites and not on people.'

No odor is, of course, a major plus for a termiticide.

'We found that a lot of our clients enjoy the fact that it is a termiticide with less odor,' says Cavanaugh. 'They don't have to consider the odor. We have used other termiticides in the past that as soon as they were applied to the soil, our clients had concerns about the odor.'

'We have drilled slabs where the fact is there have been odors even with the odor-masking agents. We made the switch over to Premise due to the fact that it had no odor.'

PACKAGING PLUS - When it comes to working in the field, PCOs consider the Premise packaging a major advantage. When Premise 75 was first

introduced to the pest control industry, the product was in four wettable powder packets within a resealable foil pack.

One water-soluble packet in 25 gallons of water provides 0.05 percent end-use concentrate, and two packets in 25 gallons of water provides 0.1 percent end-use concentrate.

Bayer has since given PCOs an alternative package, with Premise 0.5 SC in a 2.5-gallon container. In that container, 110 fluid ounces in 100 gallons of water will provide 0.05 percent end-use concentrate, while 220 fluid ounces per 100 gallons will be a 0.1 percent end-use concentrate.

All in all, the PCOs interviewed by Pest Control magazine had only good things to say about the Premise packaging. The remarks from Jim Kiening, the chief executive officer of National Bugmobiles in Victoria, Texas, are typical.

'One of our primary treaters told me that he was really comfortable with Premise because it's so convenient to use. We have 50-gallon tanks, and we just place two packs in each tank.'

By using the 50-gallon tanks and the water-soluble Premise, Kiening indicates that 'Bugmobiles tries to minimize any spill problems the company might have.'

SPECIES CONTROL - Premise is labeled for the control of all major termite species, including Eastern subterranean termites *Reticulitermes flavipes* and *Reticulitermes virginicus*; Formosan subterranean termites, *Coptotermes formosanus*; Western subterranean termites, *Reticulitermes hesperus*, and Desert subterranean termites, *Heterotermes aureus*. In addition, Premise was recently labeled for control of carpenter ants, *Camponotus* spp.

Two years ago, National Bugmobiles had a major problem with Formosan termites at a manufacturing site in the Victoria area.

'We used Premise and then treated the exposed wood with Tim-bor,' says Kiening. Bugmobiles went back at six months, one year and one-and-one-half years to inspect, and found no problems.

Many of the interviewed PCOs were also enthusiastic about the support they are provided by the Bayer sales representatives.

'They have good support,' says Cavanaugh. 'Bayer helps us out. They put on in-house training sessions and they have come out with us on large bids, such as nursing homes.'

Maybe you should put Bayer and Premise to work in your company and check out the advantages for yourself.

AB The tech. feasibility and performance of photocatalytic degradation of 4 water-soluble pesticides (diuron, imidacloprid, formetanate and methomyl) were studied at pilot scale in 2 well-defined systems of special interest because natural-solar UV light can be used: heterogeneous photocatalysis with titania and homogeneous photocatalysis by photo-Fenton. The pilot plant is made up of compound parabolic collectors (CPCs) specially designed for solar photocatalytic applications. Exptl. conditions allowed disappearance of pesticide and degree of mineralization achieved in the 2 photocatalytic systems to be compared. In order to assure that the photocatalytic results are consistent, hydrolysis and photolysis tests were performed with the 4 pesticides. The initial concentration tested with imidacloprid, formetanate and methomyl was 50 and 30 mg/L with diuron, and the catalyst concns. were 200 mg/L and 0.05mM with TiO₂ and Fe, resp. Total disappearance of the parent compds. and 90% mineralization were attained with all pesticides tested, methomyl being the most difficult to be degraded with both treatments. First-order rate consts., initial rate, time necessary for mineralizing 90% of the initial TOC and H₂O₂ consumption were calculated in all cases, enabling comparison both of treatments and of the selected pesticide reactivity.

AB An intramol. hydrogen bond between NH...O₂N in insecticide, imidacloprid (I), and its nitromethylene analog (II) was proved by NMR and IR spectra. That electron delocalization over their planar moieties was disrupted by alkylation at the imidazolidine nitrogen atom is demonstrated by the hypsochromic shifts in UV and deshielding effect in NMR spectra. Interestingly, the N-alkyl derivs. (C1-5) had greater water solubility than I, although increasing alkyl chain length decreased the solubility. The hydrophilicity of the alkyl derivs. would result from remote charge heads being formed as a result of the conjugation disruption by alkylation, while the hydrophobicity of I could be ascribed to the charge distribution over the conjugated system coupled with the intramol. H-bonding. The greater water solubility of II than I and contrastively small solubility of the cyanoimine analog are discussed based on the difference in their steric crowding.

AB Controlled-release pesticide compns. comprise mixts. of ≥ 1 water-soluble pesticides, water-insol. substances those are not softened or liquefied at $\leq 50^\circ$, and water-insol. mineral oils, natural fats and/or oils, or silicone oils, being melted or tableted and then granulated to particle size 0.1-0.5 mm. Controlled-release pesticide granules are manufactured by extrusion of the compns. Me α -(4,6-dimethoxypyrimidin-2-ylcarbamoylsulfamoyl)-o-toluate (I) 5.00, di-Me polysiloxane 0.20, and carnauba wax to 100% were mixed, tableted, and pulverized to give powder (size 100-300 μ m), 6.00% of which was kneaded with bentonite 30.00, Na ligninsulfonate 0.50, and talc to 100% and extruded to give granules. The granules (0.5 g) were put in 2 L H₂O at 20° to show release of 0.07 ppm I in 6 h and 0.42 ppm I in 24 h, vs. 0.35 ppm and 0.67 ppm, resp., for controls formulated without using

10/079000

di-Me polysiloxane and wax. The granules (at 0.3 g/are as I) showed $\geq 90\%$ control of *Monochoria vaginalis*, *Scirpus juncooides hotarui*, and *Sagittaria pygmaea*.

AB A field experiment was conducted during 1991-94 to evaluate the performance of
a new insecticide imidacloprid and other insecticides for controlling
tobacco aphid (Myzus nicotianae Blackman) on flue cured Virginia tobacco
(Nicotiana tabacum L.). Both the formulations of **imidacloprid**
(70 **water sol.** powder) and 200 soluble concs./L at 50 g
ai or acephate 750 g ai/ha as 2 foliar sprays or combination of
imidacloprid 70 **water sol.** powder at 100 g
ai/ha as plant hole treatment + 1 foliar spray of imidacloprid 200 soluble
concs./L at 50 g ai/ha effectively controlled the aphids throughout the
season and recorded better yield of cured leaf, bright-leaf and grade
index. Oxydemeton Me 0.05% foliar spray controlled the aphid effectively
only up to 8 days after spray.
